

Semiconductors, diodes, transistors

(Horst Wahl, QuarkNet presentation, June 2001)

- Electrical conductivity
 - Energy bands in solids
 - Band structure and conductivity
- Semiconductors
 - Intrinsic semiconductors
 - Doped semiconductors
 - ◆ n-type materials
 - ◆ p-type materials
- Diodes and transistors
 - p-n junction
 - depletion region
 - forward biased p-n junction
 - reverse biased p-n junction
 - diode
 - bipolar transistor
 - operation of bipolar pnp transistor
 - FET

ELECTRICAL CONDUCTIVITY

- in order of conductivity: superconductors, conductors, semiconductors, insulators
 - conductors: material capable of carrying electric current, i.e. material which has “mobile charge carriers” (e.g. electrons, ions,..)
e.g. metals, liquids with ions (water, molten ionic compounds), plasma
 - insulators: materials with no or very few free charge carriers; e.g. quartz, most covalent and ionic solids, plastics
 - semiconductors: materials with conductivity between that of conductors and insulators; e.g. germanium Ge, silicon Si, GaAs, GaP, InP
 - superconductors: certain materials have zero resistivity at very low temperature.

- some representative resistivities (ρ):

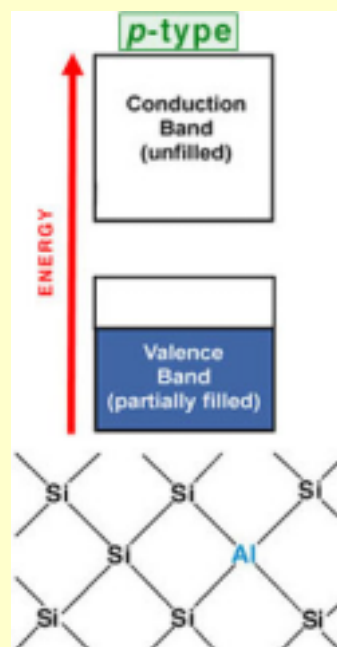

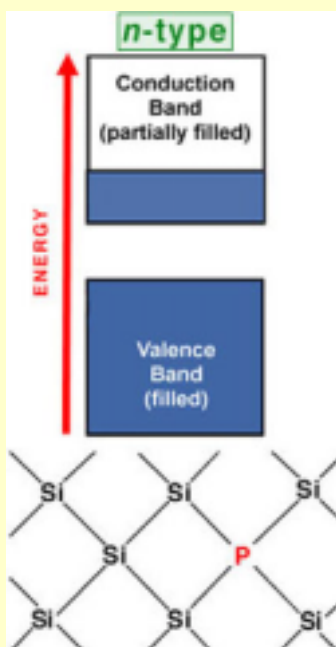

- $R = \rho L/A$, R = resistance, L = length, A = cross section area; resistivity at 20° C

	resistivity in $\Omega \text{ m}$	resistance(in Ω)($L=1\text{m}$, diam =1mm)
◆ aluminum	2.8×10^{-8}	3.6×10^{-2}
◆ brass	$\approx 8 \times 10^{-8}$	10.1×10^{-2}
◆ copper	1.7×10^{-8}	2.2×10^{-2}
◆ platinum	10×10^{-8}	12.7×10^{-2}
◆ silver	1.6×10^{-8}	2.1×10^{-2}
◆ carbon	3.5×10^{-5}	44.5
◆ germanium	0.45	5.7×10^5
◆ silicon	≈ 640	$\approx 6 \times 10^8$
◆ porcelain	$10^{10} - 10^{12}$	$10^{16} - 10^{18}$
◆ teflon	10^{14}	10^{20}
◆ blood	1.5	1.9×10^6
◆ fat	24	3×10^7

ENERGY BANDS IN SOLIDS:

- In solid materials, electron energy levels form bands of allowed energies, separated by forbidden bands
- valence band = outermost (highest) band filled with electrons ("filled" = all states occupied)
- conduction band = next highest band to valence band (empty or partly filled)
- "gap" = energy difference between valence and conduction bands, = width of the forbidden band
- Note:
 - ◆ electrons in a completely filled band cannot move, since all states occupied (Pauli principle); only way to move would be to "jump" into next higher band - needs energy;
 - ◆ electrons in partly filled band can move, since there are free states to move to.
- Classification of solids into three types, according to their band structure:
 - ◆ insulators: gap = forbidden region between highest filled band (valence band) and lowest empty or partly filled band (conduction band) is very wide, about 3 to 6 eV;
 - ◆ semiconductors: gap is small - about 0.1 to 1 eV;
 - ◆ conductors: valence band only partially filled, or (if it is filled), the next allowed empty band overlaps with it

Band structure and conductivity

INTRINSIC SEMICONDUCTORS

- semiconductor = material for which gap between valence band and conduction band is small; (gap width in Si is 1.1 eV, in Ge 0.7 eV).
- at $T = 0$, there are no electrons in the conduction band, and the semiconductor does not conduct (lack of free charge carriers);
- at $T > 0$, some fraction of electrons have sufficient thermal kinetic energy to overcome the gap and jump to the conduction band; fraction rises with temperature; e.g. at 20°C (293 K), Si has 0.9×10^{10} conduction electrons per cubic centimeter; at 50°C (323 K) there are 7.4×10^{10} .
- electrons moving to conduction band leave "hole" (covalent bond with missing electron) behind; under influence of applied electric field, neighboring electrons can jump into the hole, thus creating a new hole, etc. \Rightarrow holes can move under the influence of an applied electric field, just like electrons; both contribute to conduction.
- in pure Si and Ge, there are equally many holes ("p-type charge carriers") as there are conduction electrons ("n-type charge carriers");
- pure semiconductors also called "intrinsic semiconductors".

● **Intrinsic silicon:**

● **DOPED SEMI CONDUCTORS:**

- "doped semiconductor": (also "impure", "extrinsic") = semiconductor with small admixture of trivalent or pentavalent atoms;

n-type material

- *donor (n-type) impurities:*
 - ◆ dopant with 5 valence electrons (e.g. P, As, Sb)
 - ◆ 4 electrons used for covalent bonds with surrounding Si atoms, one electron "left over";
 - ◆ left over electron is only loosely bound \Rightarrow only small amount of energy needed to lift it into conduction band (0.05 eV in Si)
 - ◆ \Rightarrow "*n-type semiconductor*", has conduction electrons, no holes (apart from the few intrinsic holes)
 - ◆ example: doping fraction of 10^{-8} Sb in Si yields about 5×10^{16} conduction electrons per cubic centimeter at room temperature, i.e. gain of 5×10^6 over intrinsic Si.

p-type material

- **acceptor (p-type) impurities:**
 - ◆ dopant with 3 valence electrons (e.g. B, Al, Ga, In) \Rightarrow only 3 of the 4 covalent bonds filled \Rightarrow vacancy in the fourth covalent bond \Rightarrow hole
 - ◆ “p-type semiconductor”, has mobile holes, very few mobile electrons (only the intrinsic ones).
- advantages of doped semiconductors:
 - ◆ can “tune” conductivity by choice of doping fraction
 - ◆ can choose “majority carrier” (electron or hole)
 - ◆ can vary doping fraction and/or majority carrier within piece of semiconductor
 - ◆ can make “p-n junctions” (diodes) and “transistors”

DIODES AND TRANSISTORS

■ p-n JUNCTION:

- ◆ p-n junction = semiconductor in which impurity changes abruptly from p-type to n-type ;
- ◆ "diffusion" = movement due to difference in concentration, from higher to lower concentration;
- ◆ in absence of electric field across the junction, holes "diffuse" towards and across boundary into n-type and capture electrons;
- ◆ electrons diffuse across boundary, fall into holes ("*recombination of majority carriers*");
 - ⇒ formation of a "depletion region"
(= region without free charge carriers)
around the boundary;
- ◆ charged ions are left behind (cannot move):
 - negative ions left on p-side ⇒ net negative charge on p-side of the junction;
 - positive ions left on n-side ⇒ net positive charge on n-side of the junction
 - ⇒ electric field across junction which prevents further diffusion.

Pn junction

- Formation of depletion region in pn-junction:

DIODE

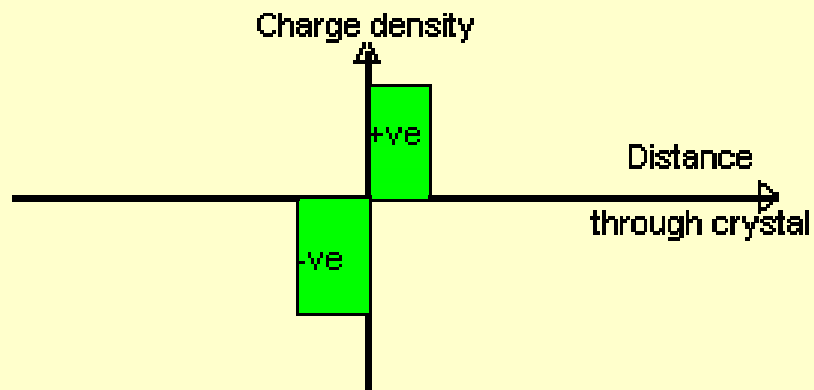

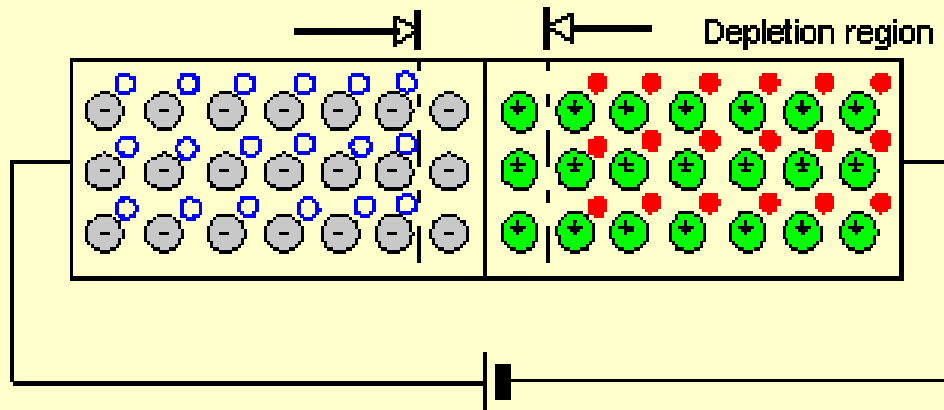

- diode = "biased p-n junction", i.e. p-n junction with voltage applied across it
- "forward biased": p-side more positive than n-side;
- "reverse biased": n-side more positive than p-side;
- forward biased diode:
 - ◆ the direction of the electric field is from p-side towards n-side
 - ◆ \Rightarrow p-type charge carriers (positive holes) in p-side are pushed towards and across the p-n boundary,
 - ◆ n-type carriers (negative electrons) in n-side are pushed towards and across n-p boundary

\Rightarrow current flows across p-n boundary

Forward biased pn-junction

- Depletion region and potential barrier reduced

Reverse biased diode

- reverse biased diode: applied voltage makes n-side more positive than p-side
 - ⇒ electric field direction is from n-side towards p-side
 - ⇒ pushes charge carriers away from the p-n boundary
 - ⇒ depletion region widens, and no current flows

- diode only conducts when positive voltage applied to p-side and negative voltage to n-side
- diodes used in "rectifiers", to convert ac voltage to dc.

Reverse biased diode

- Depletion region becomes wider, barrier potential higher

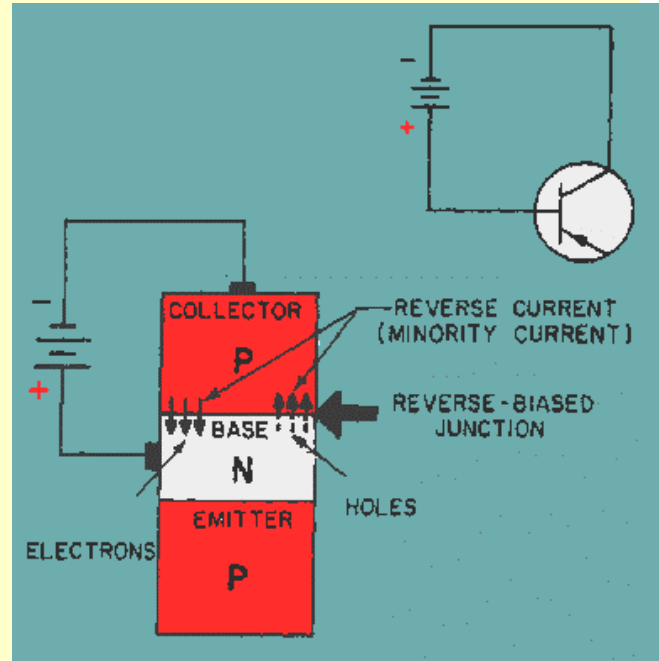

TRANSISTORS

- (bipolar) transistor = combination of two diodes that share middle portion, called "base" of transistor; other two sections: "emitter" and "collector";
- usually, base is very thin and lightly doped.
- two kinds of bipolar transistors: pnp and npn transistors
- "pnp" means emitter is p-type, base is n-type, and collector is p-type material;
- in "normal operation of pnp transistor, apply positive voltage to emitter, negative voltage to collector;

operation of pnp transistor:

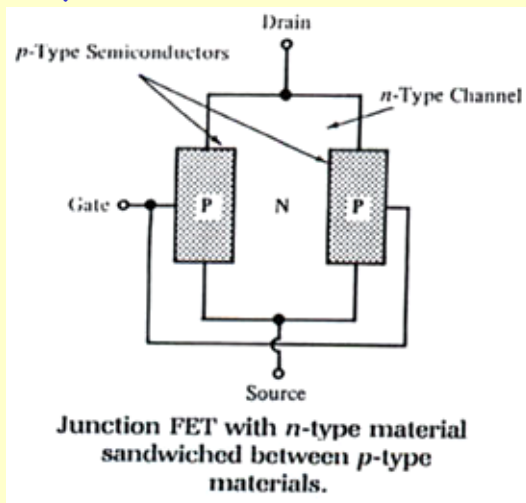

- if emitter-base junction is forward biased, "holes flow" from battery into emitter, move into base;
- some holes annihilate with electrons in n-type base, but base thin and lightly doped \Rightarrow most holes make it through base into collector,
- holes move through collector into negative terminal of battery; i.e. "collector current" flows whose size depends on how many holes have been captured by electrons in the base;
- this depends on the number of n-type carriers in the base which can be controlled by the size of the current (the "base current") that is allowed to flow from the base to the emitter; the base current is usually very small; small changes in the base current can cause a big difference in the collector current;

Transistor operation

- transistor acts as amplifier of base current, since *small changes in base current cause big changes in collector current.*
- **transistor as switch:** if voltage applied to base is such that emitter-base junction is reverse-biased, no current flows through transistor -- transistor is "off"
- therefore, a *transistor can be used as a voltage-controlled switch*; computers use transistors in this way.

“field-effect transistor” (FET)

- in a pnp FET, current flowing through a thin channel of n-type material is controlled by the voltage (electric field) applied to two pieces of p-type material on either side of the channel (current depends on electric field).

- Many different kinds of FETs
- FETs are the kind of transistor most commonly used in computers.
